then some structure has to come from external to the state space.]]]] In fact, different states can be distinguished by properties of their coherence structure. [[As noted above, the full coherence structure naturally determines the measurement induced disturbance, while the same is true for the number of coherence sectors. If we restrict ourselves to classical operations only (i.e., operations on a single input mode), then the number of sectors is easily defined through the  $n$ -mode partitioning of the coherence space, which is a property

---

of the partition. Quantum states that are invariant under the transformation of the corresponding partition naturally induce a quasi-partitioning of the coherence structure, corresponding to different kinds of invariant states. In general, the number of quasi-partitioning sectors cannot be easily determined. In the case of classical stochastic networks, it can be shown that the partitioning is identical to the [Schmidt decomposition]{} [Baillieu2016achieving]. Thus, the number of quasi-partitioning sectors, in this case, equals the Schmidt number.

---

This means that the number of quasi-partitioning sectors characterizes the number of distinguishable input states. In general, it can also be shown that the number of quasi-partitioning sectors equals the *\*strong eigenspace dimension\**, i.e., the rank of the sub-algebra of commutative operators in the corresponding invariant algebra. ]{ }]{ } [[ ]{ }]{ } The paper is organized as follows. First, we define states, coherence structures, and operations. Then, we introduce concepts of distinguished and non-distinguished states, which play a

crucial role in the proofs. The structure of the remaining sections is as follows: **[[First,]]** we **[[ ]]** **[[define]]** the class of **[[distinguished states]]** and **[[prove the main result:]]** When
